Case Study: Exploration of AI-Enabled Capabilities Embedded in Modern No-Code Applications

1. Aim

To explore the artificial intelligence (AI) capabilities integrated into modern no-code application development platforms and analyze how they improve business automation, decision-making, productivity, and application development.

2. Objectives

- To understand the concept of AI-enabled no-code applications.
- To study AI features available in modern no-code platforms.
- To analyze the implementation of AI capabilities in a real-world business application.
- To identify the benefits and limitations of AI integration.
- To evaluate the impact of AI-enabled no-code applications on business efficiency.

3. Selected Business Application

AI-Enabled Customer Support Management System using Zoho Creator

Overview

Modern no-code platforms allow users to develop applications through visual interfaces, drag-and-drop components, prebuilt templates, and workflow automation. Some platforms also integrate AI capabilities that help users analyze data, classify information, generate content, and automate repetitive tasks.

A medium-sized company receives many customer complaints and service requests through email, telephone, and online forms. Handling these requests manually can cause delays, incorrect classification, and difficulty identifying urgent issues.

To solve these problems, the company develops an AI-enabled Customer Support Management System using Zoho Creator. The application records customer requests, categorizes issues, helps prioritize complaints, and automates notifications to support staff.

Functional Requirements

Customer Module

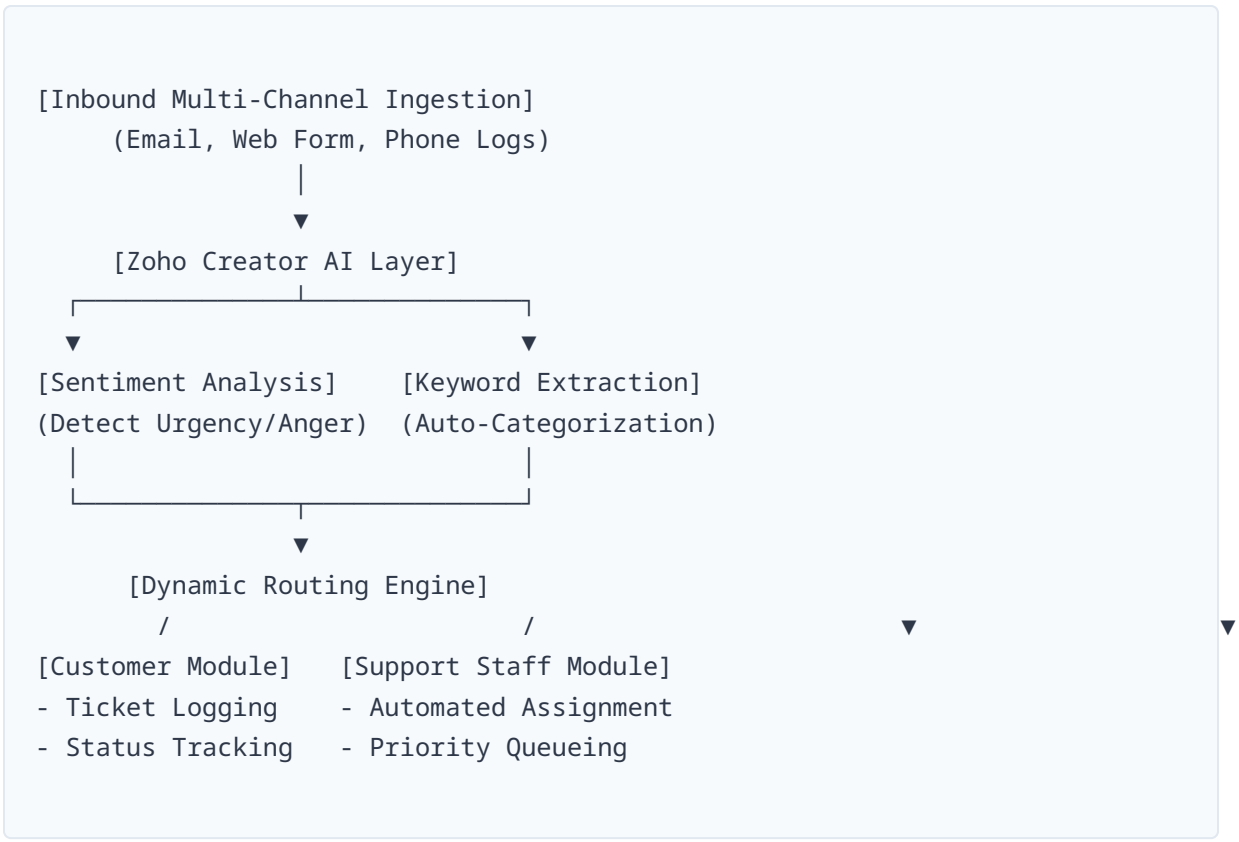
- Submit complaints and service requests.
- Enter contact details and issue descriptions.
- Track request status.
- Receive status notifications.

Support Staff Module

- View and manage customer requests.
- Assign requests to appropriate staff.
- Update resolution details.
- Monitor pending and completed requests.

4. System Architecture & AI Workflow

The system utilizes Zoho Creator's built-in AI tasks (such as Sentiment Analysis and Keyword Extraction) to process inbound requests automatically before routing them to modules.



[Inbound Multi-Channel Ingestion]
(Email, Web Form, Phone Logs)
[Zoho Creator AI Layer]
[Sentiment Analysis]
(Detect Urgency/Anger)
[Keyword Extraction]
(Auto-Categorization)
[Dynamic Routing Engine]
[Customer Module]
- Ticket Logging
- Status Tracking
[Support Staff Module]
- Automated Assignment
- Priority Queueing

5. Evaluation Matrix

Dimension	Benefits & Capabilities	Limitations & Risks
Development Velocity	Drastically reduces delivery cycles (20-40% reduction) via pre-built visual AI components instead of custom ML pipelines.	Limited customization for specialized model hyperparameter tuning or custom architectures.
Operational Efficiency	Automates manual sorting, reducing ticket misclassification rates and response latencies.	Data quality ceiling: Poorly worded or ambiguous requests degrade natural language engine accuracy.
Governance & Transparency	Centralized visual compliance management within the platform ecosystem.	Model opacity ("black-box" decisions) makes explaining specific automated routing actions complex.
